ABSTRACT

With the tremendous growth of sensitive information on cloud, cloud security is getting more important than even before. The cloud data and services reside in massively scalable data centers and can be accessed everywhere. The growth of the cloud users has unfortunately been accompanied with a growth in malicious activity in the cloud. More and more vulnerabilities are discovered, and nearly every day, new security advisories are published. Millions of users are surfing the Cloud for various purposes, therefore they need highly safe and persistent services. The future of cloud, especially in expanding the range of applications, involves a much deeper degree of privacy, and authentication. We propose a simple data protection model where data is encrypted using Advanced Encryption Standard (AES) before it is launched in the cloud, thus ensuring data confidentiality and security. In the proposed model an encryption and key exchanging mechanism has been described based on combination of Advanced Encryption Standard (AES), Triple Data Encryption Standard (DES) encryption algorithm and Advanced Diffie-Hellman algorithm which helps to enhance security in mobile cloud computing. Moreover, this paper focuses on to resolve the waste energy in the network and for this purpose offloading algorithm has been used. Since offloading algorithm has been used, data splitting can also be done in an efficient manner. Thus, it makes difficult for the intermediate person to decipher the code.

Keywords: Cloud Computing, Cloud Security, Cryptography, AES Algorithm.
1. INTRODUCTION

Cloud computing is emerging as a key computing platform for sharing resources that include infrastructure, software, applications, and business processes. Gartner predicts by 2015, 10% of overall IT security enterprise capabilities will be delivered in the cloud, with focus on messaging, web security and remote vulnerability assessment. Other focus areas will include data-loss prevention, encryption, and authentication, as technologies aimed to support cloud computing mature. The notion behind cloud computing is that work done on the client side can be moved to some unseen cluster of resources over the internet. Cloud Service Provider (CSP) maintains database and applications for the users on a remote server and provide independence of accessing them from any place through a network. There are three major cloud service categories: software-as-a-service (SaaS), platform-as-a-service (PaaS) and infrastructure-as-a-service (IaaS).

SECURITY ISSUES

Cyber crime’s effects are felt throughout the Internet, and cloud computing is an enticing target for many reasons. Providers such as Google, Microsoft, and Amazon have the existing infrastructure to deflect and survive cyber-attacks, but not every cloud has such capability. If a cyber-criminal can identify the provider whose vulnerabilities are the easiest to exploit, then this entity becomes a highly visible target. If not all cloud providers supply adequate security measures, then these clouds will become high-priority targets for cyber criminals. By their architecture’s inherent nature, clouds offer the opportunity for simultaneous attacks to numerous websites, and without proper security, hundreds of websites could be compromised through a single malicious activity.

Cloud computing security includes a number of issues like multi tenancy, data loss and leakage, easy accessibility of cloud, identity management, unsafe API’s, service level agreement inconsistencies, patch management, internal threats etc. It is not easy to enforce all the security measures that meet the security needs of all the users, because different users may have different security demands based upon their objective of using the cloud services.
2. RELATED WORKS

Cloud storage provides users with great benefits and advantages. It provides better accessibility, for instance it enables them to access data from any device connected to the internet. There is no need for users to bring their physical storage devices wherever they are and they can use any computer for saving and retrieving their information. It enhances teamwork and collaborative efforts by allowing team members to access shared data. In addition to that, cloud storage is cost saving due to not having to buy or maintain expensive hardware. Also, it can be used for backup, archival and disaster recovery purposes. Moreover, the data are stored on many servers to guarantee a sustainable service to the clients so that they are able to access their data at any time.

DEPSKY: dependable and secure storage in a cloud-of-clouds: Bessaniet al.3 proposed DEPSKY a secure and reliable system that takes a responsibility in improving the availability, integrity and confidentiality of the stored information by encrypting, encoding and replicating data on different clouds that form a cloud-of-clouds. The system was implemented using four cloud storage service providers (Amazon S3, Windows Azure, Nirvanix and Rackspace) and PlanetLab to run clients that access the service from numerous places around the world. The paper outlines four drawbacks of the individual cloud 1) Loss of availability 2) Loss and corruption of data 3) Loss of privacy 4) Vendor lock-in. It describes how the DEPSKY system succeed in dealing with them by using an effective set of Byzantine quorum system protocols, cryptography, secret sharing, erasure codes and the variety which comes from using more than a single cloud.

CloudSafe: Storing Your Digital Asset in the Cloud-based Safe: Zhang et al.7 proposed CloudSafe to enhance availability and confidentiality of the stored information in the cloud through encrypting and encoding data into several cloud storage providers.

In order to make a safe, dependable and quick data access repository possible, CloudSafe offers a cloud-based personal digital asset safe service which delivers the valuable assets between several cloud providers by using erasure coding and cryptography. The storage providers are: Dropbox, GoogleDrive, Microsoft SkyDrive and SugarSync. According to Zhang et al., the availability improves due to using erasure coding to distribute the data on several cloud providers, in order to recover data access...
when a provider fails. AES24 have been used for encrypting and decrypting data to keep data confidentiality. A Secure Erasure Code-Based Cloud Storage System with Secure Data Forwarding: Lin et al. 4 proposed a threshold proxy re-encryption scheme and combined it with a non-centralized erasure code to design a secured distributed storage system that offers secure and strong data storage and recovery. In addition, the formulated storage system allows users to forward their data to the server and to other users. The proposed system provides strong confidentiality and secrecy of messages in storage servers. The re-encryption scheme boosts encoding operations over encrypted messages and forwarding operations over encoded and encrypted messages. But each of these solutions has many limitations.

Seiger et al. 5 has a few limitations like that it needs more management and resources, keys are managed by the provider and data is exposed to hacking attacks when a user sends it to the servers of the service provider or in case the hacker breaks the transmission security protocol. Bessani et al. 9 requires a lot of physical resources thus increases costs. Another limitation of the paper is that keys could be managed by many servers which will increase risk. Somani et al. 6 also has a few limitations for example it uses the RSA encryption technique that is less secure and slow in encrypting and decrypting large amount of data. RSA contains a public and a private key therefore the solution needs key management from a third party, which will increase risk.

3. PROPOSED SYSTEM

Cloud computing is likely to suffer from a number of known vulnerabilities, enabling attackers to either obtain computing services for free or steal information from cloud users. In the world of computing, security and privacy issues are a major concern and cloud computing is no exception to these issues.

Our target is to handle two issues the user encounter when using cloud computing services. The first one is users concerns about hacking threats whether internally or externally. The other one is the infeasibility of encrypting all data without taking into consideration its confidentiality degree. Therefore, we propose a framework that allows the users to encrypt own data using a key that is not available for the provider. In addition we encrypt data bases on the degree of confidentiality.
4. ADVANTAGES

- The user decides to use cloud services and migrate his data on the cloud.
- User submits his service requirements with CSP’s and chooses provider offering best specified services.
- When migration of data to the chosen CSP happens and in future whenever an application uploads any data on the cloud, the data is encrypted and then sent.
- The encryption process is done using AES algorithm.
- Once encrypted, data is uploaded on the cloud.

5. SYSTEM MODEL

![System Model Diagram]

**Implementing AES Algorithm**

AES is a block cipher with a block length of 128 bits. It allows three different key lengths: 128, 192, or 256 bits. We propose AES with 128 bit key length. The encryption process consists of 10 rounds of processing for 128-bit keys. Except for the last round in each case, all other rounds are identical. 16 byte encryption key, in the form of 4-byte words is expanded into a key schedule consisting of 44 4-byte words. The 4 x 4 matrix of bytes made from 128-bit input block is referred to as the state array. Before any round-based processing for encryption can begin, input state is XORed with the first four words of the schedule. For encryption, each round consists of the following four steps:

- **SubBytes** – a non-linear substitution step where each byte is replaced with another according to a lookup table (S-box).
- **ShiftRows** – a transposition step where each row of the state is shifted cyclically a certain number of times.
MixColumns – a mixing operation which operates on the columns of the state, combining the four bytes in each column.

AddRoundKey – each byte of the state is combined with the round key; each round key is derived from the cipher key using a key schedule.

COMPARING AES WITH OTHER ALGORITHMS

The fact that the cipher and its inverse use different components practically eliminates the possibility for weak and semi-weak keys in AES, which is an existing drawback of DES. Also, nonlinearity of the key expansion practically eliminates the possibility of equivalent keys in AES. A performance comparison amongst AES, DES and Triple DES for different microcontrollers shows that AES has a computer cost of the same order as required for Triple DES [9]. Another performance evaluation reveals that AES has an advantage over algorithms-3DES, DES and RC2 in terms of execution time (in milliseconds) with different packet size and throughput (Megabyte/Sec) for encryption as well as decryption. Also in the case of changing data type such as image instead of text, it has been found that AES has advantage over RC2, RC6 and Blowfish in terms of time consumption [8].

PERFORMANCE EVALUATION

We have built a simulator to evaluate the proposed framework. The simulator was developed using Microsoft.Net C# with the support of library System Security which is implemented within C# and using the default settings in Microsoft .NET Framework 4.5. We have done all necessary validations and verifications. All simulation experiments were conducted using the same platform: Intel(R) Core(TM) i7-2600K CPU, processor speed 3.40GHz, and RAM of 3 GB. The operating system is Microsoft Windows NT 6.1.7601 SP1. We used the provided classes in Microsoft .Net environment to simulate 3DES, AES128 and AES256. Security library that provides the functionality of a cryptographic cipher used for encryption and decryption.
We have tested the performance of symmetric algorithms including AES128, AES256 and 3DES. The performance evaluation is based on the time needed to encrypt data blocks with different sizes varied between 2GB and 10 GB. The results showed that AES128 has outperformed the other algorithms in terms of speed in encrypting data blocks as it has the lowest processing time compared to other algorithms.

CLOUDLETS

With the emerging cloud computing and the explosive growth of mobile applications, mobile cloud computing (MCC) has become a promising technology for mobile services. In MCC, mobile devices, such as smartphones and tablets, can offload data storage and computational task on to the cloud through wireless communications, thereby overcoming their limited capabilities regarding processing power, storage capacity, and battery lifetime.

The remote cloud provides data storage and computing service while mobile devices are clients to access the service through wireless networks, mainly cellular and WLAN (Wireless Local Area Network). When accessing a remote cloud is costly due to long WAN (Wide Area Network) latencies, a mobile user can exploit nearby computers that are well-connected to the Internet and uses cloud service over a high-bandwidth WLAN. The vast computation resources on remote cloud servers can enable computation intensive applications, such as image processing for video games, optical character recognition (OCR), and augmented reality, run on mobile devices. WiFi or Bluetooth to form a mobile cloudlet, in which mobile devices (referred to as cloudlet nodes) can be computing service providers as well as clients of the service. By dividing the task among cloudlet nodes, the initiator mobile device could speed up computing and conserve energy. Users can get direct cloud computing access instantly through interactions among one another, eliminating the communication latency and data roaming charges introduced by the cellular networks. Mobile cloudlet is appealing to users pursuing a common goal in group activities.
such as multimedia sharing for audience at an event and language translation for a group of tourists in a foreign country. The major concern of using mobile cloudlet resides in the limited computing power of mobile devices and the unstable connections between cloudlet nodes due to node mobility.

6. PROBLEM STATEMENT

Organizations can use services and data stored as and when required at any physical location outside their own control. This facility raised the various security issues like privacy, confidentiality, integrity etc., and demanded a trusted computing environment wherein data confidentiality can be maintained. To get rid of the same and to induce trust in the computing, there is need of a system which provides authentication, verification and encrypted data transfer, hence maintaining data confidentiality.

7. CONCLUSIONS

In this paper, we have proposed an efficient confidentiality-based cloud storage framework that enhances the processing time and assures confidentiality and integrity through data classification and applying TLS, AES and SHA based on the type of classified data. The efficiency of our proposed framework has been shown through conducting simulations. The simulation results show that our framework achieves better processing time while assuring data confidentiality and integrity. As part of our future work, we plan to enhance our framework by considering other aspects. This includes automatic data classification and the use of different cryptographical algorithms such as asymmetric public key, RSA, and Elliptic curve cryptography that could provide higher degree of confidentiality and security. A strong user authentication framework for cloud computing with Advanced Diffie-Hellman algorithm, AES, 3DES and Digital Signature. In the proposed work a offloading algorithm, we incorporate the data caching mechanism and improve task management strategies with dynamic energy scheduling algorithm which shows that the high efficiency of our algorithm allows the mobile device to calculate the optimal offloading decision at the local end with much lower time complexity and energy consumption.
